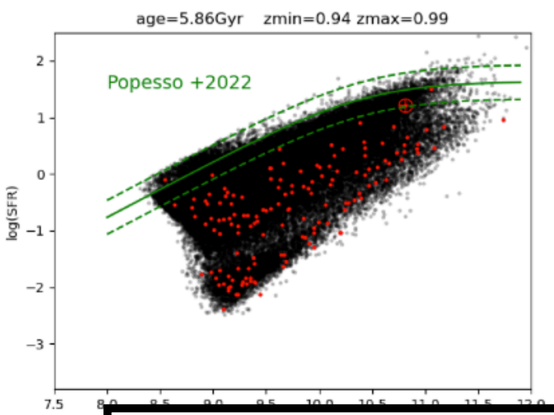
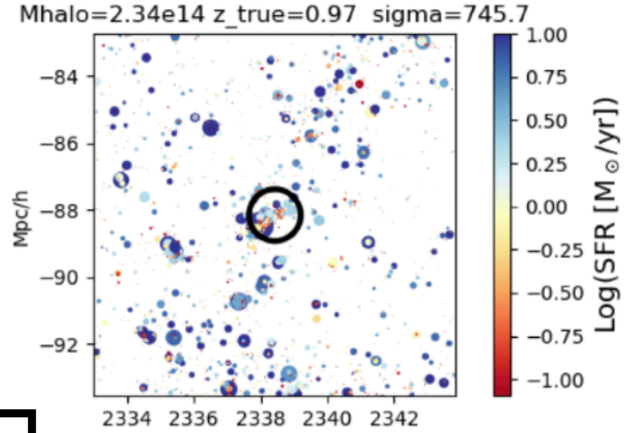
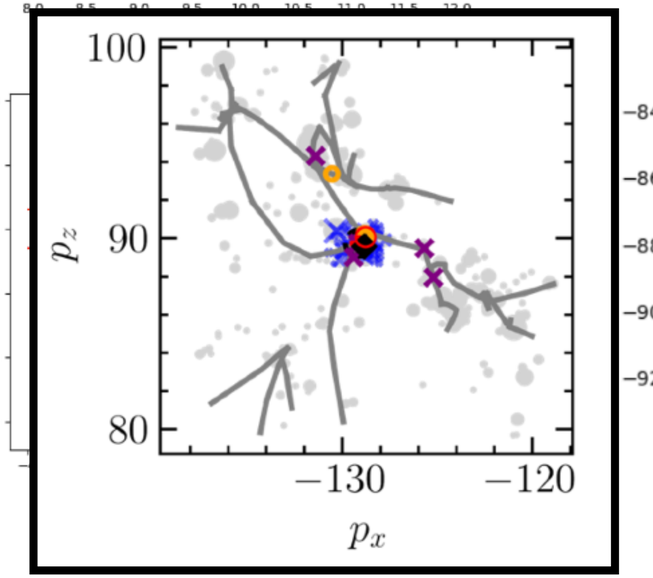
Extend this type of analysis to higher redshift with Euclid ?

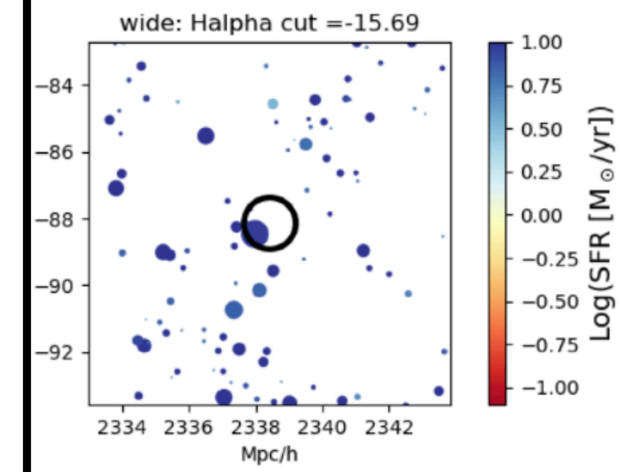
The Euclid survey will cover 15,000 deg^2 with photometry in visible and near-infrared bands

Billions of galaxies — 30 million with spectroscopic redshifts at $0.9 < z < 1.8$









Hα selected galaxies are mostly star-forming i.e. may not be as good a tracer of the cosmic web compared to SDSS LRG sample

Work in progress inside the Euclid consortium in collaboration with K. Kraljic, C. Laigle, U. Kuchner et al.

Assess cosmic filaments detectability with DisPerSE

Cosmic filaments around clusters with photometric redshifts
